FTAP Homework 9

Zachary Fogelson July 23, 2015

Reading

```
gdp <- read.xls("gdp.xls", skip = 17)
gdpGrowth <-
tb <- read.csv("tbill.csv")

sp500 <- read.csv("table.csv")
sp500$DateTime <- as.Date(sp500$Date, "%Y-%m-%d")
sp500 <- sp500[order(sp500$DateTime, decreasing=F),]
sp500 <- sp500[complete.cases(sp500),]

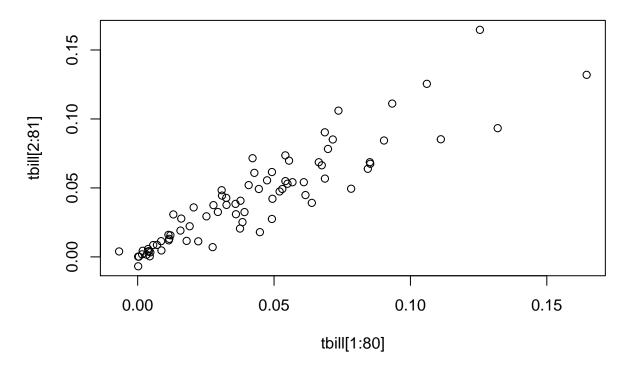

hp <- read.csv("table (1).csv")
hp$DateTime <- as.Date(hp$Date, "%Y-%m-%d")
hp <- hp[order(hp$DateTime, decreasing=F),]
hp <- hp[complete.cases(hp),]

spRet <- diff(log(sp500$Adj.Close))
hpRet <- diff(log(hp$Adj.Close))</pre>
```

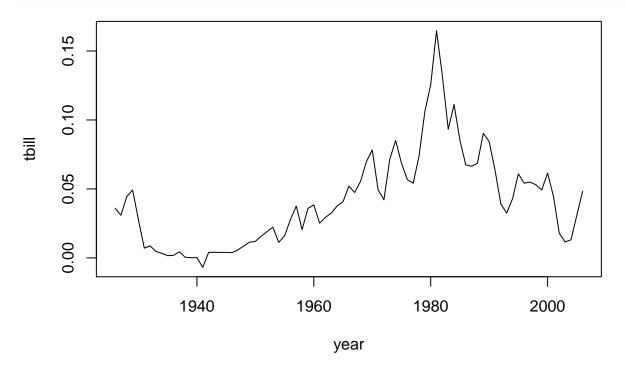

Problem 1

Set up

```
year<-tb$Year
tbill<-tb$tbill
plot(tbill[1:80], tbill[2:81])</pre>
```

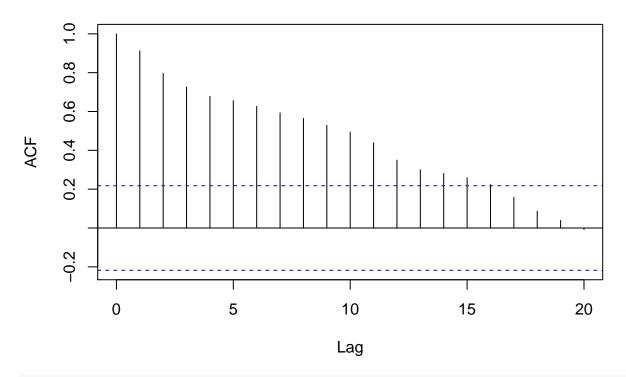

plot(year,tbill, type="1")

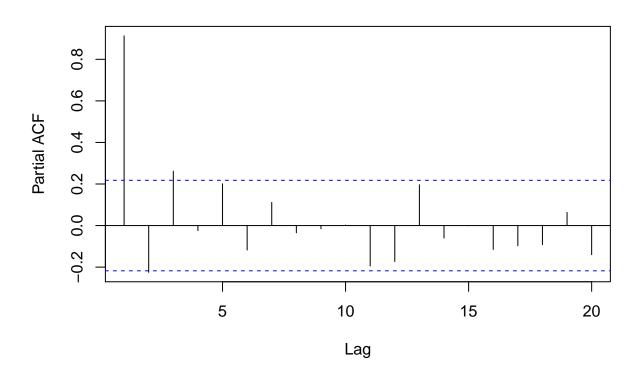

acf(tbill,lag.max=20)

Series tbill

pacf(tbill,lag.max=20)

Series tbill

```
ar<-arima(tbill,order=c(1,0,0))</pre>
summary(ar)

a
p<-predict(ar,n.ahead=15)
```

Predictions

 $0.0477050\ 0.0471221\ 0.0465954\ 0.0461194\ 0.0456892\ 0.0453005$

kable(head(data.frame(Predictions = c(p\$pred))))

 ${f b}$ As we predict further out, our prediction for our errors changes over time:

Lets find the forecast error variance:

$$Var\left(e_{t}^{k}\right) = Var\left(\sum_{j=0}^{k-1} \beta_{1}^{j} \varepsilon_{t+k-j}\right)$$

but the ε_t are iid. So...

$$Var(e_{t}^{k}) = \sum_{j=0}^{k-1} \beta_{1}^{2j} Var(\varepsilon_{t+k-j}) = \sigma^{2} \sum_{j=0}^{k-1} \beta_{1}^{2j} = \frac{\left(1 - \beta_{1}^{2k}\right)}{\left(1 - \beta_{1}^{2}\right)} \sigma^{2}$$

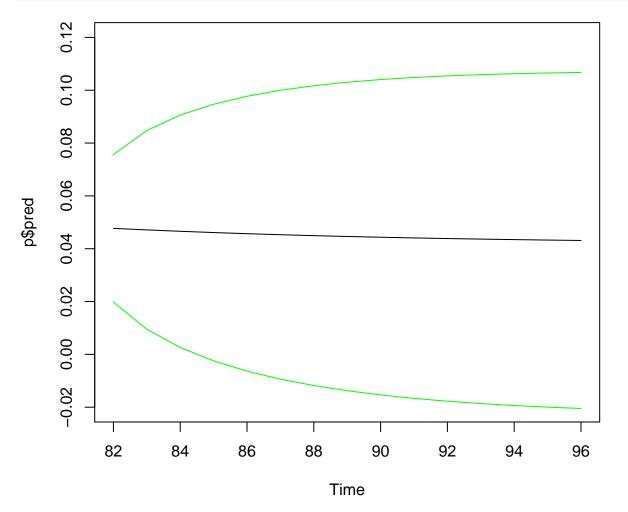

```
p<-predict(ar,n.ahead=15)
kable(head(data.frame(Variance = c(p$se^2))))</pre>
```

Variance

 $0.0001948\ 0.0003540\ 0.0004839\ 0.0005900\ 0.0006767\ 0.0007474$

 \mathbf{c}

```
plot(p$pred, ylim = c(-.02,.12))
lines(p$pred + 2 * p$se, col = "green")
lines(p$pred - 2 * p$se, col = "green")
```

Problem 2

```
plot.ts(log(gdp$VALUE))
```

a

```
grwRate <- diff(log(gdp$VALUE))
mean(grwRate)</pre>
```

[1] 0.007908376

```
rwfPred <- rwf(log(gdp$VALUE), h=4, drift=T, level=c(80,95), fan=FALSE, lambda=NULL)
rwfPred$model$drift</pre>
```

[1] 0.007908376

```
kable(head(data.frame(Upper = c(as.numeric(exp(rwfPred$upper[,2]))))))
```

Upper

 $16270.24\ 16529.38\ 16762.41\ 16982.96$

```
kable(head(data.frame(Upper = c(as.numeric(exp(rwfPred$lower[,2]))))))
```

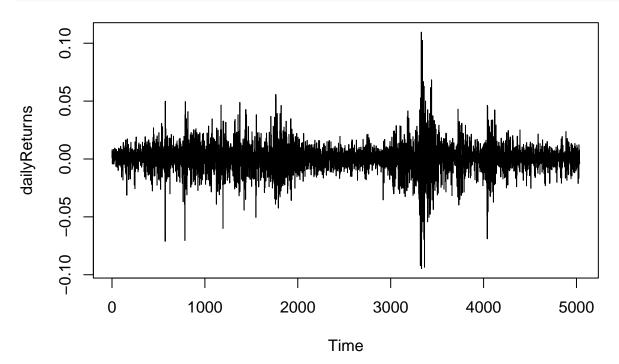

Upper

 $15665.60\ 15665.84\ 15694.34\ 15737.48$

Problem 3

a

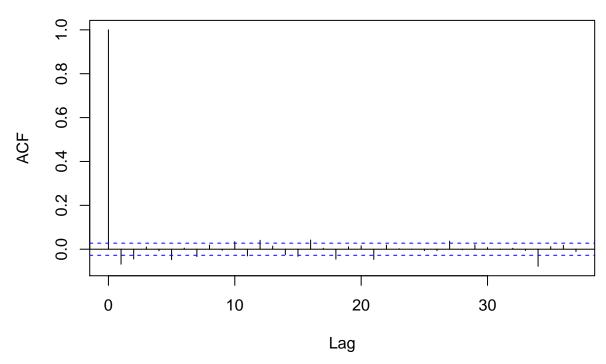

```
spRet <- diff(log(sp500$Adj.Close)) # This should have already been defined but R doesn't think so
dailyReturns <- spRet
plot.ts(dailyReturns)</pre>
```

 \mathbf{b}

acf(dailyReturns)

Series dailyReturns

Because the auto-correlations are consistently higher than the critical value, we reject the null hypothesis that the difference in absolute daily returns is not auto-correlated. Namely, we concluded that there is a relationship between the absolute value of yesterday's returns and today's returns.

 \mathbf{c}

```
kurtosis(dailyReturns)[1]
```

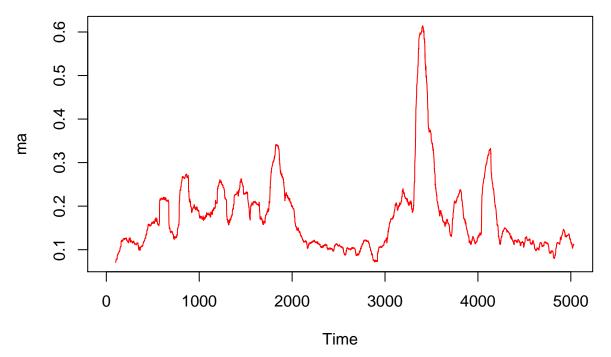

[1] 7.983142

R returns the excess Kurtosis over and above a normal distribution. Therefore, we can see that the returns have MUCH fatter tails than a normal distribution would suggest.

Problem 4

 \mathbf{a}

```
r2=252*dailyReturns*dailyReturns
ar=sqrt(252)*r2
ma <- sqrt(filter(r2,rep(1/100,100), sides=1))
plot(ma,type="l",col="red")</pre>
```

 \mathbf{b}

ma <- sqrt(filter(r2,rep(1/252,252), sides=1))
plot(ma,type="l",col="red")</pre>

Problem 5

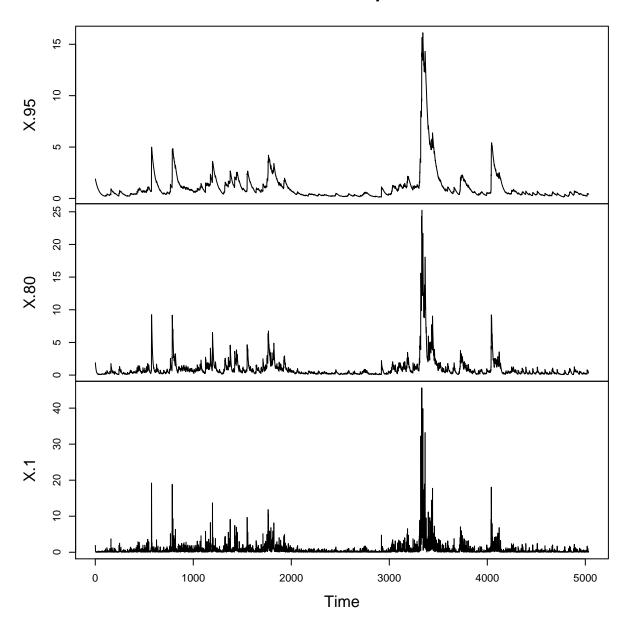

a, b, c

```
rmvar <- matrix(0,nrow=length(ar),ncol=1)
rmvar[1,1] <- var(ar)
for (i in 2:length(rmvar)){
    rmvar[i,1] <- (lambda*rmvar[i-1,1])+((01-lambda)*ar[i-1]^2)
}
sqrt(rmvar)
}

plot.ts(data.frame(".95" = c(smoother(.95)), ".80" = c(smoother(.8)), ".1" = c(smoother(.1))), main = ".</pre>
```

Smoother Comparison

smoother <- function(lambda){</pre>

Problem 6

```
a
```

 \mathbf{c}

 \mathbf{c}

```
myGarch <- function(r, h){
   .00045 + .04^2*r^2 + .94*h
}
myGarch(.04, .03)

## [1] 0.02865256

b
myGarch(.01, .03)

## [1] 0.02865016</pre>
```

 $\sigma^2 = \frac{\omega}{1 - \alpha - \beta}$

```
.00045/(1-.04-.94)

## [1] 0.0225

Problem 10

a

The mean of the profile should be the expectation of the linear combination of the weighted portfolio:

$$\mu_w = w * \mu_{sp} + (1 - w) * r_f$$

The variance of the profile should be the variance of the linear combination of the weighted portfolio:

$$\sigma^2 = w^2 * \sigma_{sp}^2 + (1 - w)^2 * \sigma_{r_f}^2$$

By definition, the variance of the risk free rate is 0:

$$\sigma^2 = w^2 * \sigma_{sp}^2$$

b

$$U(w) = (w * \mu_{sp} + (1 - w) * r_f) - \frac{\lambda}{2} (w^2 * \sigma_{sp}^2)$$

Maximize by setting the derivative to 0:

$$\frac{dU}{dw} = \mu_{sp} - r_f - \lambda w \sigma_{sp}^2 = 0$$
$$\lambda = \frac{\mu_{sp} - r_f}{w \sigma_{sp}^2}$$

Therefore, if $\lambda = 5$:

$$5 = \frac{\mu_{sp} - r_f}{w\sigma_{sp}^2}$$
$$w = \frac{\mu_{sp} - r_f}{5\sigma_{sp}^2}$$

 \mathbf{c}

```
\begin{array}{l} \text{mean(diffSp)} \\ \text{var(diffSp)} \\ \text{w} \leftarrow & (\text{mean(diffSp)} - (.02/252) \ )/ \ (5 * \text{var(diffSp)}) \\ \text{print(w)} \\ \\ \mu_{sp} = 2.6509879 \times 10^{-4} \\ \sigma_{sp}^2 = 1.4968278 \times 10^{-4} \\ r_f = 7.9365079 \times 10^{-5} \\ \text{d} \\ \\ \text{w} \leftarrow & (\text{mean(diffSp)} - (.02/252) \ )/ \ (5 * \text{var(diffSp)}) \\ \text{U} \leftarrow & (\text{w} * \text{mean(diffSp)} - (1-\text{w}) * .02/252) - 5/2*(\text{w}) \\ \end{array}
```

Problem 11

 \mathbf{a}

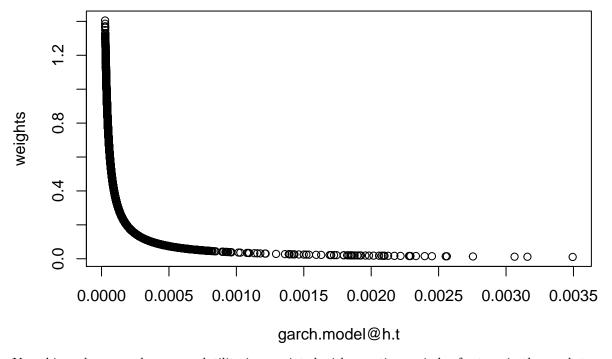

```
w <- (mean(diffSp) - (.02/252) )/ (5 * var(diffSp))

utility <- function(h){
    w*mean(diffSp) + (1-w)*.02/252 - 5/2 * (w^2*h)
}

weight <- function(h){
    (mean(diffSp) - .02/252) / (5 * h)
}

garch.model <- garchFit(~garch(2,2),data=diffSp,trace = F)
    weights <-mapply(weight, as.numeric(garch.model@h.t))

plot(garch.model@h.t, weights)</pre>
```

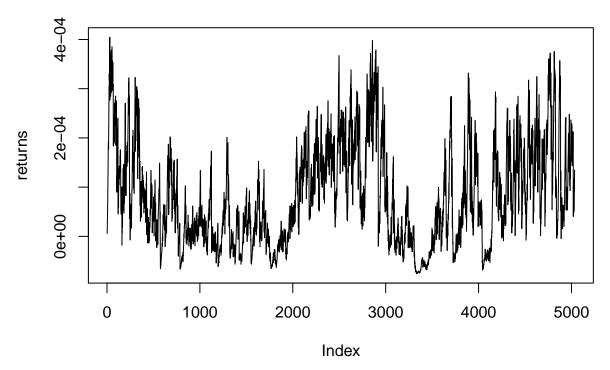

Yes, this makes sense because volatility is associated with negative periods of return in the market.

b

```
realized <- function(weight){
   weight * mean(diffSp) - (1 - weight)*(.02/252)
}
returns <- mapply(realized, weights)

plot(returns, type = "1")</pre>
```

 \mathbf{c}

```
meanRet <- mean(returns)
weightedVar <- 5/2 * mean((returns - meanRet)^2)

meanRet - weightedVar

## [1] 8.566098e-05

d

us <- returns - 5/2*(returns - meanRet)
sd(us)/sqrt(length(us))

## [1] 2.153042e-06</pre>
```

```
## [1] 288138.1
```

I am clearly rejecting the null, at the moment, (however, due to the lateness) I am going to claim this is a implementation error and with more sleep, I would have written better R.

uBar <- mean(returns) - 5/2*sum((returns - meanRet)^2)

print((uBar - U) / (sd(us)/sqrt(length(us))))
